

Features

- Low Power CK410M clock synthesizer
- Drop-in replacement to existing CK410M design
- Support Intel mobile PCI_Express chipsets
- Integrated CK_SSCD function to provide additional Spread Spectrum support for Alviso GMCH
- CLK_REQ# inputs to support hot insertion for Express-Card
- 3.3 Volt Power Supply
- 64 pin TSSOP Package

Output Summary

- 2- differential CPU clock outputs @ 0.7V
- 1 - selectable differential CPU clock output @ 0.7V or CLKREQ# input
- 1 - selectable LCDCLK_SS or SRC clock output @ 0.7V
- 8 - differential Serial Reference Clock (SRC) clock outputs @ 0.7V
- 1 - differential 96MHz clock output @ 0.7V
- 1 - single-ended 48MHz clock output @ 3.3V
- 6 - single-ended 33MHz clock outputs @ 3.3V
- 2 - single-ended 14.318MHz clock output @ 3.3V

Pin Description

Pin #	Name	Type	Description
1	PCI_REF_SEL/PCI_3	I/O, SE	PCI clock output. When PCI_REF_SEL is sampled HIGH during VTT_PWRGD# assertion, it will configure REF_0/PCI_1 as PCI_1 output. When PCI_REF_SEL is sampled LOW, it will configure REF_0/PCI_1 as REF_0 output.
2	PCI_4	O, SE	PCI clock output.
3	PCI_5	O, SE	PCI clock output.
4	VSS_PCI	GND	Ground for outputs.
5	VDD_PCI	PWR	3.3V power supply for outputs.
6	PCI_6	O, SE	PCI clock output.
7	SEL_LCDCLK#/PCI_F1	I/O, SE	Free running PCI clock output. When SEL_LCDCLK# is sampled HIGH during VTT_PWRGD# assertion, it will configure LCDCLK_SS/SRC_0 as SRC_0 output. When SEL_LCDCLK# is sampled LOW during VTT_PWRGD# assertion, it will configure LCDCLK_SS/SRC_0 as LCDCLK_SS output.
8	PCI_SRC_STOP#	I	3.3V LVTTTL input for PCI_SRC_STOP#.
9	VTT_PWRGD#/PD	I	VTT_PWRGD# is a 3.3V LVTTTL input. It acts as a level sensitive strobe to latch the FS pins and other multiplexed inputs. After VTT_PWRGD# assertion, it becomes a real time input for asserting power down (active high).
10	VDD_48	PWR	3.3V power supply for outputs.
11	FS_A/USB_48MHz	I/O, SE	USB clock output. Frequency Select input to determine CPU output frequency.
12	VSS_48	GND	Ground for outputs.
13	DOT_96	O, LP-DIF	Low Power 96 MHz DOT clock output.
14	DOT_96#	O, LP-DIF	Low Power 96 MHz DOT clock output.
15	FS_B/TEST_MODE	I	Frequency Select input to determine CPU output frequency. When in test mode, FS_B/TEST_MODE will configure outputs to run at REF or Hi-Z. 0 = Hi-Z, 1 = REF
16	VDD_LCDCLK	PWR	3.3V power supply for outputs.
17	VSS_LCDCLK	GND	Ground for outputs.
18	LCDCLK_SS/SRC_0	O, LP-DIF	Configurable differential clock output. LCDCLK_SS is a differential output with programmable spread spectrum percentage for GMCH's DREF_SSCLK.
19	LCDCLK_SS#/SRC_0#	O, LP-DIF	Configurable differential clock output. LCDCLK_SS is a differential output with programmable spread spectrum percentage for GMCH's DREF_SSCLK.
20	SRC_1	O, LP-DIF	Low Power Differential Serial Reference Clock output.
21	SRC_1#	O, LP-DIF	Low Power Differential Serial Reference Clock output.
22	SRC_2	O, LP-DIF	Low Power Differential Serial Reference Clock output.
23	SRC_2#	O, LP-DIF	Low Power Differential Serial Reference Clock output.
24	VDD_SRC	PWR	3.3V power supply for outputs.
25	VSS_SRC	GND	Ground for outputs.
26	SRC_3	O, LP-DIF	Low Power Differential Serial Reference Clock output.
27	SRC_3#	O, LP-DIF	Low Power Differential Serial Reference Clock output.

Block Diagram

Frequency Select Pins (FS_A, FS_B, FS_C)

Host clock frequency selection is achieved by applying the appropriate logic levels to Frequency Select (FS) inputs prior to VTT_PWRGD# assertion (as seen by the clock synthesizer). Upon VTT_PWRGD# being sampled low by the clock chip (indicating processor VTT voltage is stable), the clock chip samples the FS input values. VTT_PWRGD# employs a one-shot functionality in that once a valid low on VTT_PWRGD# has been sampled, all further VTT_PWRGD#, FS input transitions will be ignored. Please refer to Frequency Select Table for different CPU frequency configurations.

FS_C/TEST_SEL Clarification

The FS_C/TEST_SEL input is a three level input. When voltage levels are below Vih min., the frequency selection latched on the assertion of VTT_PWRGD# is determined by Vih_FS and Vil_FS thresholds in the DC Electrical Characteristics section. However, if the voltage level sampled during VTT_PWRGD# assertion is equal or greater than Vih min., the device will invoke test clock operation. Test clock operation is used in bed of nails testing to verify clock functionality. Test clock operation can be invoked in two ways, via writing a logic “1” to the “Test Clock Mode Entry Control” bit in the control register or by placing a logic high equal or greater than Vih minimum on the FS_C/TEST_SEL pin prior to the assertion of VTT_PWRGD#. Once test clock operation has been invoked, the device will remain in test clock operation until power is cycled with the voltage on FS_C/TEST_CLK is less than Vih minimum.

TEST_SEL Hardware Control Via FS_B/TEST_MODE pin

Once test clock operation has been invoked, the FS_B/TEST_MODE pin will select between the Hi-Z and REF mode as shown in the table below using the standard low voltage Vih_FS and Vil_FS thresholds.

Table 2. Test Mode Selection Table

TEST_MODE	CPU	SRC/ LCDCLK	PCIF/PCI	REF	DOT_96	USB_48
1	REF	REF	REF	REF	REF	REF
0	Hi-Z	Hi-Z	Hi-Z	Hi-Z	Hi-Z	Hi-Z

TEST_CLK Software Control via Control Register bits

When the “Test Clock Mode Entry Control” bit in the control register is set high, the device will invoke test clock operation. Once test clock operation has been invoked via software control, the Test_Mode bit in the control register will select between Hi-Z and REF modes taking priority over the external FS_B/TEST_MODE pin.

PD (Power Down) Clarification

The VTT_PWRGD#/PD pin is a dual function pin. During initial power-up, the pin functions as VTT_PWRGD#. Once VTT_PWRGD# has been sampled low by the device, the pin assumes PD functionality. The PD pin is an asynchronous active high input used to shut off ALL clocks cleanly prior to shutting off power to the device. This signal is synchronized internal to the device prior to powering down the clock synthesizer. When PD is asserted high, all clocks are driven to a low value and held prior to turning off the VCOs and the crystal oscillator.

Table 3. PD Functionality

PD	CPU	CPU#	SRC LCDCLK_SS	SRC# LCDCLK_SS#	PCIF/PCI	DOT_96	DOT_96#	USB	REF
0	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal
1	Iref*2 or Float	Float	Iref*2 or Float	Float	Low	Iref*2 or Float	Float	Low	Low

PD# - Assertion

When PD is sampled high by two consecutive rising edges of CPU#, all single-ended outputs will be held low on their next high to low transition and differential clocks will be held high or tristated (depending on the state of the control register drive mode bit) on the next "Diff clock#" high to low transition. When the PD drive mode bit corresponding to the differential (CPU, SRC and DTOT_96) clock output of interest is programmed to '0', the clock output will be held with the "Diff clock" pin driven high at 2 x Iref, and "Diff clock#" tristated. If the control register PD drive mode bit corresponding to the output of interest is programmed to '1', then both the "Diff clock" and the "Diff clock#" are tristated.

Figure 1. Power Down Assertion

PD De-assertion

The power-up latency is less than 1.8ms. This is the time from the de-assertion of the PD pin or the ramping of the power supply until the time that stable clocks are output from the clock device. All differential outputs stopped in a tristate condition resulting from power down will be driven high in less than 300us of PD de-assertion to voltage greater than 200mV.

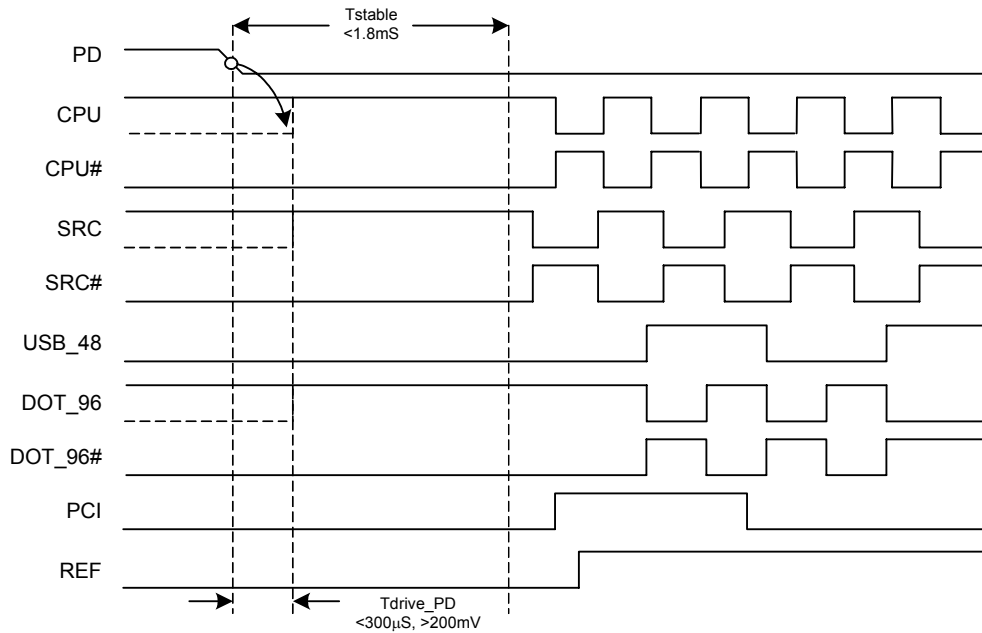

Figure 2. Power Down De-assertion

PCI_STOP# Clarification

The PCI_STOP# signal is an active low input used for cleanly stopping and starting the PCI and SRC outputs while the rest of the clock generator continues to function. The PCIF and SRC clocks are special in that they can be programmed to ignore PCI_STOP# by setting the register bit corresponding output of interest to become free-running. Outputs set to be free-running will ignore both PCI_STOP# pin and the PCI_STOP# register bit.

PCI_STOP Control via Software Control

The purpose of the PCI_STOP# control register bit is to allow system designers to implement PCI_STOP functionality in one of two ways. Either the system designer can choose to use the externally provided PCI_STOP# pin to assert or de-assert PCI_STOP mode or the system designer can pull the external pin high and use software to control PCI_STOP functionality via SMBus.

Table 4. PCI_STOP# Functionality

PCI_STOP#	CPU	CPU#	SRC	SRC#	PCIF/PCI	DOT_96	DOT_96#	USB	REF
1	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal
0	Normal	Normal	Iref*6 or Float	Low	Low	Normal	Normal	Normal	Normal

PCI_STOP# Assertion (Transition from '1' to '0')

The clock chip will sample the PCI_STOP# signal on a rising edge of PCIF clock. After detecting the PCI_STOP# asserting low, all PCI and stoppable PCIF clocks will latch low on their next high to low transition. After the PCI clocks are latched low, the SRC clocks, (if set to be stoppable) will latch high at Iref*6 (or tristate if the SRC_STOP# drive mode bit in the control register is set high) upon its next low to high transition and SRC# will latch low. The Tsu is the setup time required by the clock generator to correctly sample the PCI_STOP# assertion, this time is 10ns minimum.

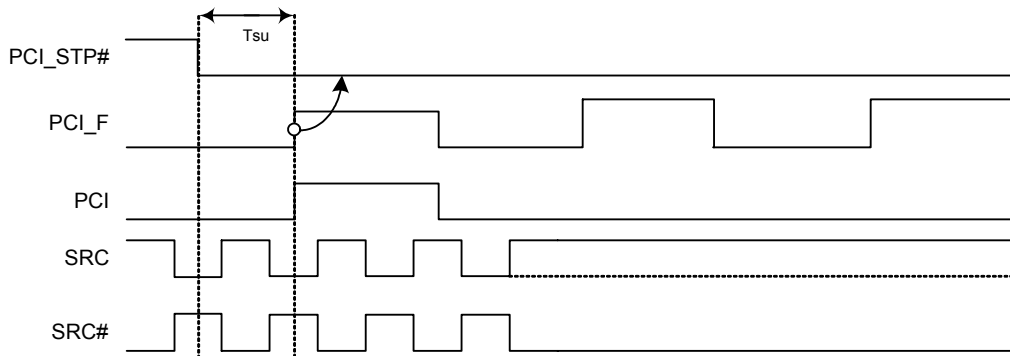

Figure 3. Assertion of PCI_STOP#

PCI_STOP# De-Assertion (Transition from '0' to '1')

The de-assertion of the PCI_STOP# signal is to be sampled on the rising edge of the PCIF free running clock domain. After detecting PCI_STOP# de-assertion, all PCI, stoppable PCIF and stoppable SRC clocks will resume in a glitch free manner. The PCI and SRC clock resume latency will match the one PCI clock latency required for PCI_STOP# entry. If the SRC_STOP drive mode bit is programmed to '1' (tristate), then the stopped SRC clocks will be driven high within 15ns of PCI_STOP# de-assertion. The Tsu is the setup time required by the clock generator to correctly sample the PCI_STOP# de-assertion, this time is 10ns minimum.

Figure 4. De-Assertion of PCI_STOP#

CPU_STOP# Clarification

The CPU_STOP# signal is an active low asynchronous input used for cleanly stopping and starting the CPU outputs while the rest of the clock generator continues to function.

Table 5. CPU_STOP# Functionality

PCI_STOP#	CPU	CPU#	SRC	SRC#	PCIF/PCI	DOT_96	DOT_96#	USB	REF
1	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal	Normal
0	Iref*6 or Float	Low	Normal	Normal	Normal	Normal	Normal	Normal	Normal

CPU_STOP# Assertion (Transition from '1' to '0')

When CPU_STOP# is asserted, all CPU outputs that are set in the control registers to be stoppable are to be stopped after their next transition. When the control register CPU_STOP tristate bit corresponding to the output of interest is programmed to '0', the final state of the stopped CPU signals is "CPU = High" and "CPU# = Low". There will be no change to the output drive current values, CPU will be driven high with a current value equal 6*Iref, and CPU# will not be driven. When the control register CPU_STOP tristate bit corresponding to the output of interest is programmed to '1', the final state of the stopped CPU clock is low, both CPU clock and CPU clock# outputs will not be driven.

Figure 5. Assertion of CPU_STOP#

CPU_STOP# De-Assertion (Transition from '0' to '1')

All differential outputs that were stopped are to resume normal operation in a glitch free manner. The maximum latency from the de-assertion to active outputs is between 2-6 CPU clock periods. If the control register CPU_STOP# tristate bit corresponding to the output of interest is programmed to '1', then the stopped CPU outputs will be driven high within 10ns of CPU_STOP# de-assertion to a voltage greater than 200mV.

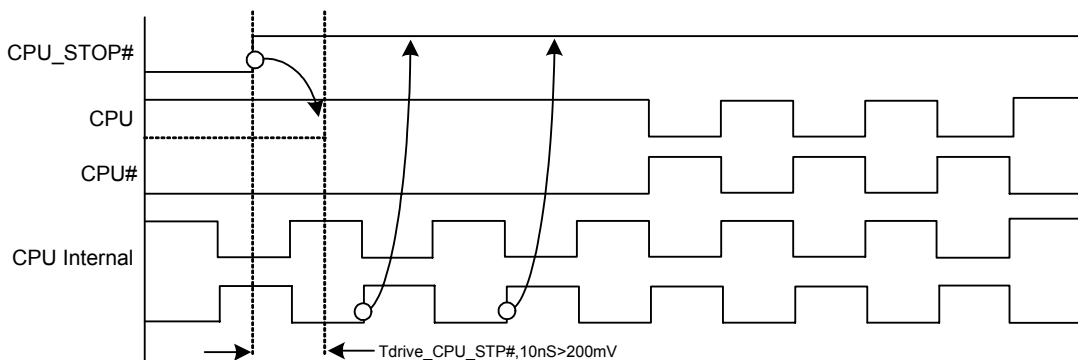

Figure 5. CPU_STOP# De-Assertion

VTT_PWRGD# Operation

VTT_PWRGD# is an active low signal to indicate when the processor VTT voltage has stabilized. The significance of the VTT supply being stable is that only after VTT is stable are the processor frequency select (FS) and VID bits become valid.

Figure 6. Clock Generator Power Up/Run State Diagram

Serial Bus Interface

A two-wire serial interface is provided as the programming interface for the clock synthesizer. The serial interface is fully compliance to the SMBus 2.0 specification. The registers associated with the two-wire interface initializes to their default setting upon power-up, and therefore use of this interface is optional.

The serial interface supports block write and block read operation from any SMBus master devices. For block write and block read operations, the bytes must be accessed in sequential order from lowest to highest byte (most significant bit first) with the ability to stop after any complete byte has been transferred. The block write and block read protocol is outlined in *Table 6*. The slave receiver address is 11010010 (D2h).

Crystal Recommendations

The SLG8LP462B requires a **Parallel Resonance Crystal**. Substituting a series resonance crystal will cause the SLG8LP462B to operate at the wrong frequency and violate the ppm specification. For most applications there is a 300ppm frequency shift between series and parallel crystals due to incorrect loading.

Table 8. Crystal Recommendations.

Frequency (Fund)	Cut	Loading	Load Cap	Drive (max.)	Shunt Cap (max.)	Motional (max.)	Cut Accuracy (max.)	Temp Stability (max.)	Aging (max.)
14.31818MHz	AT	Parallel	20pF	0.1mW	5pF	0.016pF	35ppm	30ppm	5ppm
